

## **Moose Jaw Boom Lift Safety Training**

Moose Jaw Boom Lift Safety Training - Boom lifts fall under the category of aerial lifting device or elevated work platform. Most commonly used in construction, industry, and warehousing; the boom lift is really versatile that it can be used in virtually whatever setting.

Elevated work platforms allow personnel to get into work places which would be inaccessible otherwise. There is inherent danger in the operation of these devices. Employees who operate them must be trained in the proper operating techniques. Accident prevention is paramount.

The safety aspects which are included in boom lift operation are included in our Boom Lift Training Programs. The course is suitable for those who operate self-propelled elevated work platforms and self-propelled boom supported elevated work platforms. Upon successful completion of the course, participants would be given a certificate by a person who is certified to confirm finishing a hands-on evaluation.

Industry agencies, federal and local regulators, and lift manufacturers all play a role in providing information and establishing standards in order to help train operators in the safe utilization of elevated work platforms. The most important ways in preventing accidents connected to the utilization of elevated work platforms are as follows: performing site assessments; checking machinery; and putting on safety gear.

Important safety factors when operating Boom lifts:

Operators should observe the minimum safe approach distance (or also called MSAD) from power lines. Voltage could arc across the air to be able to find an easy path to ground.

To be able to maintain stability when the platform nears the ground, a telescopic boom has to be retracted before lowering a work platform.

Boom lift workers should tie off to guarantee their safety. The harness and lanyard apparatus must be connected to manufacturer provided anchorage, and never to other wires or poles. Tying off may or may not be needed in scissor lifts, depending on particular local rules, employer guidelines or job risks.

The maximum slope will be specified by the manufacturer. Workers should avoid working on a slope, if possible. When the slope is beyond recommended conditions, the lifting device must be winched or transported over the slope. A grade can be measured easily by laying a straight board or edge of at least 3 feet on the slope. Afterward a carpenter's level can be laid on the straight edge and raising the end until it is level. The per-cent slope is attained by measuring the distance to the ground (also referred to as the rise) and dividing the rise by the length of the straight edge. Next multiply by one hundred.
